

WSP - Web System Programming

Laboratory 12 – React+Vite 2/2

Implementation of forms and service, use of routing.

Complete the following tasks using React and Vite and `react-router-dom` module. The application should be functionally similar to Lab 08, but with a different graphical interface and asynchronous backend data access.

1. The program should consist of a few components organized like below.

2. In the menu bar, you must have at least the following options: Articles, Category, About (with author details).
3. Create a service to manage the collection of articles and categories. The service must communicate with the API controller in the backend.
4. Instead of the MainPanel, depending on the menu option, it must be either ArticlesPanel, CategoryPanel, or AboutComponent.
5. For the left-hand panels, display a list of articles/categories with a button to create a new one.
6. Use the DetailsPanel to implement operations for modifying, deleting, viewing, and creating a new article/category. Create a separate component for each operation and use it in the second-level routing.
7. For editing articles, create a dropdown list with categories if you want to use them in the form.

Deadline 1: meeting 15 (max 100 points)
